

Programming Question

You are given three arrays of integers **a**, **b**, and **c**, and an array of characters **signs** consisting of '+' and '-' signs. All of these arrays have the same length.

Your task is to return a boolean array **output** of the same length, where **output[i] = true** if the result of applying **signs[i]** to **a[i]** and **b[i]** is equal to **c[i]**, and **false** otherwise.

In other words

For each index **i**, check if:

- **signs[i] == '+'** and **a[i] + b[i] == c[i]**
- **signs[i] == '-'** and **a[i] - b[i] == c[i]**

If the corresponding equation is correct, set **output[i]** to true; otherwise set it to false.

Constraints / Note

You are not expected to provide the most optimal solution, but a solution with time complexity not worse than **O(a.length²)** will fit within the execution time limit.

Example

For example, if the arrays contain several integer values and **signs** specifies '+' or '-' at each position, evaluate the corresponding arithmetic expression independently for every index and return the resulting boolean array.
